

Relationship between Exchange Rates and Stock Prices – GCC Perspectives

Jassim Aladwani*

*Email: Jassim1@hotmail.com

ABSTRACT

The main objective of this paper is to investigate the relation between the exchange rates and stock prices of the six GCC countries. The empirical results indicate that there is cointegration between stock prices and exchange rates in Kuwait, Bahrain and Oman. The Granger causality test reveals that exchange rates (in terms of the GBP) cause stock prices in all GCC countries, while stock prices cause exchange rates in Oman and Kuwait. Conversely, the empirical evidence indicates that exchange rates (in terms of the JPY) cause stock prices in Kuwait, while there is only one case of bidirectional causality between stock prices and exchange rates (the case of Oman).

Keywords: Exchange Rate, Stock Price, Basket Currency, Peg Currency, Cointegration, Granger Causality JEL Classifications: A10, A12, C13

1. INTRODUCTION

The relationship between exchange rates and stock prices has attracted the attention of policy makers, economists and investors, as these financial prices play a crucial role in the macro economy (Nieh and Lee 2001). Although the available evidence largely indicates the absence of a long-term relationship between stock prices and exchange rates (Sohrabiab and Bahmani, 1992; Nieh and Lee 2001; Ramasamy and Yeung, 2005), this relationship continues to be a source of contention and investigation.

The empirical work conducted this study is based on time series for exchange rates and stock prices. Although these financial prices behave in a similar fashion, as they are driven by news and other factors, there is a notable difference in their behaviour. Stock prices tend to move along a secular upwards trend arising from the growth and development of the economy, but this secular trend is interrupted by cycles of bear and bull markets. In contrast, exchange rate movements are dominated by cycles and do not exhibit long-run trends. Unless a country is experiencing hyperinflation, its exchange rate cannot fall or rise without bounds over a long period. This is particularly the case for the GCC currencies, which are pegged to the US dollar, except for the Kuwaiti currency, which is pegged to a basket of currencies. Therefore, it is of interest to determine whether changes in stock prices cause changes in exchange rates, or vice versa.

2. LITERATURE REVIEW

Theoretical considerations lead to the proposition that exchange rates and stock prices are related (Dornbusch and Fischer, 1980; Aggarwal, 2003; Yau and Nieh, 2006). The portfolio balance approach indicates that the exchange rate is influenced by the mechanism of the stock market. That is, portfolio theories focus on the significant role of capital account transactions in determining exchange rate dynamics (Ajayi et al., 1998; Hatemi and Irandoust, 2002; Phylaktis and Ravazzolo, 2005; Hatemi and Roca, 2004; Thoma, 2008). However, there is neither a theoretical nor an empirical consensus on the relationship between stock prices and exchange rates, and it is not clear whether this relationship is causal in one direction or both directions.

According to Johnston and Sun (1997), who examined exchange rate risk pricing in the US stock market, US companies exhibit significant cross-sectional differences in their exposure to foreign exchange risk. Abdalla and Murinde (1997) evaluated the interaction between stock prices and exchange rates in some emerging markets, including the Philippines, Pakistan, India and Korea. Their results showed the presence of unidirectional causality from stock prices to exchange rates in the Philippines, India and Pakistan, as well as causality from exchange rates to stock prices in Korea. Hatemi and Roca (2005) criticised previous empirical research for using sample periods characterised by normal conditions instead of good and bad times. They pointed out that stock prices and exchange rates were strongly related during the period before the Asian financial crisis. The direction of causality was from stock prices to exchange rates in the case of Thailand and Indonesia, and from exchange rates to stock prices in the case of Malaysia or for the period encompassing the financial crisis.

Ajay et al. (1998) examined the causal relation between exchange rates and stock prices using the Granger causality test. They found unidirectional causality from changes in the exchange rate to stock return differential in all industrial markets, whereas a consistent causal linkage was observed in emerging stock markets, with the exception of the Philippines and Indonesia, where the direction of causality was from exchange rates to stock prices. Hatemi and Irandoust (2002) employed the Granger test to study the relation between stock prices and exchange rates in Sweden. They found that causality is unidirectional, running from the currency market to the stock market. In fact, they found that an increase in Swedish stock prices leads to currency depreciation. Another study that supports the portfolio balance approach is that of Phylaktis and Ravazzolo (2005), who examined the underlying propositions for Thailand, Indonesia, Hong Kong, Malaysia and Indonesia. Their found no long-term relationship between stock prices and real exchange rates in all countries. Further, they found that stock prices are positively related to exchange rates. Bodnar and Bartov (1994), Nieh and Lee (2001), Muhammad and Rasheed (2002), Phylaktis and Ravazzolo (2005) and Uddin and Rahman (2009) indicated that exchange rates are not influenced by changes in stock prices, and vice versa. In contrast, others have found bidirectional causality between exchange rates and stock prices (Sohrabiab and Bahmani, 1992; Ajayi and Mougoue, 1996; Aydemir and Demirhan 2009).

Research on this issue is predominantly based on two-variable regressions to study the relationship between exchange rates and stock prices; thus, the problem of missing variables has been neglected. Nonetheless, previous studies have established that the exclusion of relevant variables from a system might invalidate the causality inference between the variables of an incomplete system. The underlying argument—that any change in one of the variables causes changes in another variable drawn from a bivariate causality test—may be invalid because of the omission of significant variables (Caporale et al. 2004).

3. METHODOLOGY

This section presents the methodology used, starting with the unit root test, followed by cointegration analysis and then causality.

3.1. Unit Root Test

Specifying a regression equation in levels rather than first differences may be problematical. Granger and Newbold (1974) presented some results indicating that when time series variables are non-stationary, using levels may result in a non-constant mean over time and a residual that is highly auto-correlated, with a low Durbin-Watson statistic. For this reason, Granger and Newbold recommended the use of the first difference of each variable before running the regression. Plosser and William (1978) noted that in an undifferenced regression, the disturbance term is nonstationary and is not well behaved. They concluded that it is better to work with differenced economic data rather than data in levels for most economic time series. Therefore, one must exercise care when using data in levels rather than differences. Griffiths et al. (1993) argued that "the usual statistical properties of least squares hold only when the time series variables involved are stationary." Accordingly, non-stationary time series have to be differenced before performing econometric analysis.

In this paper, we use the augmented Dickey-Fuller (ADF) unit root test. According to Schwert (1989), the ADF test with long lags outperforms the corresponding model without lags. Therefore, the model used in this study is specified as follows:

$$\Delta \mathbf{y}_{t} = \alpha + \boldsymbol{\varphi} \mathbf{y}_{t-1} + \sum_{i=1}^{n} \boldsymbol{\beta}_{i} \ \Delta \mathbf{y}_{t-i} + \boldsymbol{\varepsilon}_{t}$$
(1)

Where Δ is the first difference operator. The test is applied to stock prices SP₁ and exchange rates ER₁. The corresponding equations are:

$$\Delta SP_{t} = \beta_{0} + \varphi_{1}SP_{t-1} + \sum_{i=1}^{n} \beta_{i} \Delta SP_{t-i} + \varepsilon_{1t}$$
⁽²⁾

And:

$$\Delta ER_{t} = \alpha_{0} + \varphi_{2} ER_{t-1} + \sum_{i=1}^{n} \alpha_{i} \Delta ER_{t-i} + \varepsilon_{2t}$$
(3)

Where,

 $\Delta SP_t = SP_t - SP_{t-1}$ and $\Delta ER_t = ER_t - ER_{t-1}$. The null of non-stationarity (unit root) is H_0 : $\varphi=0$, whereas the alternative of stationarity (absence of unit root) is H_1 : $\varphi<0$.

3.2. Cointegration Testing

Cointegration is used to detect the existence of an equilibrium relationship between any two or more variables. Engle and Granger (1987) proposed a two-step approach to cointegration when the variables (stock prices and exchange rates) are I(1). The first step involves estimating the long-run equation by ordinary least squares (OLS) and then applying the ADF test to the residuals. Engle and Granger (1987) provided the critical values of the test statistics. Therefore, the test involves two equations:

$$\mathbf{y}_{t} = \delta_{0} + \delta_{1} \mathbf{x}_{t} + \mathbf{u}_{t} \tag{4}$$

And:

$$\Delta \mathbf{u}_{t} = \Delta \mathbf{u}_{t-1} + \sum_{i=1}^{n} \mathcal{O}_{i} \Delta \mathbf{u}_{t-i} + \mathbf{v}_{t}$$
 [5)

The OLS estimates of the coefficients of the cointegrating regression are super consistent in the presence of cointegration,

even though the usual standard error is not reliable. If the residual is found to be non-stationary, then the two variables (exchange rate and stock price) are not cointegrated and the findings are possibly spurious. However, if the residual is stationary, then there is a meaningful long-run relationship between exchange rates and stock prices.

3.3. Causality Testing and the Vector Auto-regression (VAR) Model

To examine the relationship between stock prices and exchange rates, we must determine whether the exchange rate causes the stock price to change, or vice versa. In this paper, we use the VAR model to examine linear causality between these two variables. The use of VAR models can be justified in terms of the meaning of causality in economics, where it is not really causality in the same sense as it is in natural sciences. In economics (and finance) something causes something else because it occurs before the something else. A variable causes another if its lagged values can explain variation in the dependent variable over and above what can be explained by lagged dependent variables. For this reason a model with lagged dependent and explanatory variables is needed to conduct causality testing.

For this purpose, the following two equations are used if there is no integration between the two variables;

$$\Delta SP_{t} = \beta_{0} + \sum_{i=1}^{n} \beta_{1i} \Delta SP_{ti} + \sum_{i=1}^{n} \beta_{2i} \Delta ER_{ti} + \varepsilon_{1t}$$
(6)

And:

$$\Delta ER_{t} = \beta_{0} + \sum_{i=1}^{n} \beta_{1i} \Delta ER_{t-i} + \sum_{i=1}^{n} \beta_{2i} \Delta SP_{t-i} + \varepsilon_{2t}$$
⁽⁷⁾

The possibilities are as follows: (i) causality from stock prices to exchange rates ($SP_t \rightarrow ER_t$), (ii) causality from exchange rates to stock prices ($ER_t \rightarrow SP_t$), (iii) independence between exchange rates and stock prices, and (iv) and feedback causality between stock prices and exchange rates. If exchange rates and stock prices are cointegrated, the VAR model must include an error correction term (ECT), in which case the equations become:

$$\Delta SP_{t} = \beta_{0} + \vartheta_{1} \left(SP_{t-1} - \delta ER_{t-1} \right) + \sum_{i=1}^{n} \beta_{1i} \Delta SP_{t-i} + \sum_{i=1}^{n} \beta_{2i} \Delta ER_{t-i} + \varepsilon_{st}$$
(8)

And:

$$\Delta ER_{t} = \alpha_{0} + J_{2} \left(SP_{t-1} - \delta ER_{t-1} \right) + \sum_{i=1}^{n} \alpha_{1i} \Delta ER_{t-i} + \sum_{i=1}^{n} \alpha_{2i} \Delta SP_{t-i} + \varepsilon_{st}$$
(9)

Where ϑ_1 and ϑ_1 are the coefficients on the ECTs.

4. DATA

This empirical work is based on monthly time series data on exchange rates and stock prices over the period 1 January 2000-31 December 2013. The data were collected from data stream, with the exception of the share prices of Bahrain, Oman and the UAE, which were obtained from each country's stock exchange website. Table 1 lists the countries, exchange rates and stock market indices.

5. EMPIRICAL RESULTS

5.1. Unit Root Test—Results

The results obtained using the ADF test for the unit root are displayed in Table 2. H_0 is that ER_t and SP_t contain a unit root against H_a (alternative hypothesis) that both variables are stationary under consideration. Table 3 shows that the null hypothesis—that SP_t and ER_t have a unit root—cannot be rejected. Nevertheless, the H_0 of unit roots is rejected after the exchange rate and stock price variables have been put in first difference. This suggests that the variables are I(1).

Figures 1-18 show the exchange rates series and stock price series of the GCC countries. As shown in these figures, the exchange rates have similar cycles, which is due to the pegging of the exchange rates to the USD. That is, when the USD depreciates (appreciates)

The critical values for cointegrating relations (with a constant in the cointegrating vector) are estimated using the Engle–Granger methodology. Critical values are interpolated using the response surface in Engle and Granger (1987)

against the GBP and JPY, GCC currencies depreciate (appreciate) against the same currencies. Kuwait is the only exception, as the currency is pegged to a basket of currencies.

GCC stock prices increased gradually during the sample—for example, from 2000 to 2008, stock prices increased by more than 120%. However, after the global financial crisis, most GCC stock markets declined gradually until the end of 2012. Although GCC stock prices and exchange rates have been moving in the same direction, there is no indication of stock indices being responsive to exchange rates, and vice versa. In addition, the figures show how stock prices and exchange rates in first differences behave.

5.2. Cointegration Analysis—Results

After testing for stationarity of stock prices series and exchange rates series, we moved to cointegration analysis. Two methods

were used to test for cointegration: The residual-based method and the error correction method.

5.3. Bivariate Cointegration Test Analysis: Residual-based Method

For residual-based bivariate cointegration analysis, equation 8 is estimated, and the residual is extracted and tested for the unit root. Table 3 shows the ADF statistics corresponding to the maximum Akaike's Information Criterion for the ADF regressions of the residual ranging from order 0 to order 10.

The results reported in Table 3 show that, with the exception of that between the market index and exchange rate series in Kuwait, Bahrain and Oman, failed to reject the null hypothesis of no cointegration. Hence, cointegration appears between the Kuwait stock market index and exchange rate (KWD/JPY) series, between

the Kuwait stock market index and exchange rate (KWD/GBP) series, between the Bahrain stock market index and exchange rate (BHD/JPY) series, and between the Oman stock market index and exchange rate (OMR/JPY) series.

5.4. Bivariate Cointegration Analysis: Error Correction Model

According to Granger's representation theorem, cointegration implies and is implied by the existence of a valid error correction representation. Hence, it is possible to test for cointegration by estimating the error correction model (ECM) and testing its validity. The test of cointegration depends on the significance of ϑ_1 and ϑ_2 in equations 8 and 9 respectively. It is worth noting that the coefficients must be significantly negative in the ECM. The maximum lag(n) length of the ECM is initially specified as four for stock prices and two for exchange rate variables.

For bivariate cointegration analysis, the estimation results for equations 11 and 12 are reported in Table 4, which shows evidence for cointegration between stock market indices and exchange rates (against JPY) for most GCC countries, except

Bahrain and Oman. In addition, there are only two cases of cointegration (Kuwait and Bahrain) between stock prices and exchange rates (against GBP).

5.5. Granger Causality Testing

Having tested for cointegration, we now test for causality between the exchange rates and stock prices. For this purpose, equations 9 and 10 are estimated. Prior to applying Granger causality tests, we need to select the appropriate lag length for exchange rates and stock prices using the Schwarz Bayesian information criterion. The optimum lag length for testing causality from exchange rates to stock prices (ER \rightarrow SP) is three for exchange rates and two for stock prices. The optimum lag for testing causality from stock prices to exchange rates is four for stock prices and seven for exchange rates. The results are presented in Tables 5-10.

The findings presented in Tables 5-10 vary according to the market. For instance, it is noticeable that exchange rates cause stock prices

results of the Granger causality test between stock prices and exchange rates (in terms of JPY) are reported in Tables 11-16. The results show that bidirectional causality exists between stock prices and exchange rates in the case of Oman. In addition, exchange rates cause stock prices in the case of Kuwait—that is, only unidirectional causality is detected between exchange rates and stock prices.

6. CONCLUSION

In this paper, we estimated the relationship between exchange rates and stock prices in GCC countries during the period 2000-2013. The empirical results show that there is cointegration between stock prices and exchange rates in Kuwait, Bahrain and Oman. The Granger causality test reveals that exchange rates (in terms of GBP) cause stock prices in all GCC countries, while stock prices cause exchange rates in Oman and Kuwait. In contrast,

the empirical evidence indicates that exchange rates (in terms of JPY) cause stock prices in Kuwait, while there is only one case of bidirectional causality between stock prices and exchange rates (in the case of Oman).
